## FOREWORD

We are pleased to present this second annual compilation of data from the National Water Quality Network of the Public Health Service. It has been gratifying to note the many uses which the first year's data have served.

We believe the data will continue to gain in significance with the passage of time. Some trends in pollution levels are already discernible. New trends will be defined as more data are accumulated.

The water quality measurement program must be sensitive to problems of the day, to new techniques, new parameters, and other developments. This year the Network has added Strontium-90 and heavy metals analyses to the examinations made during the first year. Other determinations will continue to be added as their usefulness develops.

Again we are deeply grateful to the many local, State, and Interstate agencies and industrial concerns who are participating, and whose contribution to this program in a large measure assures its success.

## NATIONAL WATER QUALITY NETWORK

The Public Health Service program for providing fundamental information on the quality of the Nation's waters stems from the provisions of Section 4(a) of Public Law 660, enacted on July 9, 1956 which states that "the Surgeon General shall in cooperation with other Federal, State and local agencies having related responsibilities collect and disseminate basic data on chemical, physical, and biological water quality insofar as such data or other information relate to water pollution and the prevention and control thereof."

To fulfill this responsibility, the Network provides for collection, interpretation, and dissemination of

- a. Information on changes in water quality at key points in river systems as such quality may be affected by changes in water use and development
- b. Continuous information on the nature and extent of pollutants affecting water quality
- c. Data which will be useful in the development of comprehensive water resources programs
- d. Data which will assist State, interstate and other agencies in their water pollution control programs and in the selection of sites for legitimate water uses

Approximately 80 sampling locations were established for the initial phase of this program, starting October 1, 1957. To conform with existing practices in other water resources activities, the data year was established to cover the period October 1 to September 30 of the following year.

Each location satisfies one or more of the following criteria:

- a. Major waterways used for public water supply, propagation of fish and wildlife, recreational purposes and agricultural, industrial and other legitimate uses
- b. Interstate, coastal, and international boundary waters
- c. Waters on which activities of the Federal Government may have an impact

Final locations of sampling stations are fixed after discussions with local, State, Federal and other agencies having related interests.

Active local participation is an important part of this operation and assures the development of the maximum amount of information of value locally and nationally. The cost of the program is shared by the Federal Government with State and local agencies, through the latter's contributions of laboratory time and sampling manpower. Specifically, the State and local agencies perform most of the conventional chemical analyses and collect samples for the newer, more complex combinations. The Public Health Service, in turn, performs the more complex determinations and makes the results available to the participants. In addition, the consultation, training facilities, and other resources of the Public Health Service are available to the cooperating agencies.

The locations of sampling stations in operation during the data year October 1, 1958 to September 30, 1959, are shown in Figure 1. A description of the stations with the participating agencies and other pertinent information, is presented in Table 1.

The following combinations, selected after careful screening, and consultation with the various agencies concerned with water quality management and water resources development, are considered to be of greatest value in meeting the objectives of the program:

- a. Radioactivity
  - (1) Gross Alpha
  - (2) Gross Beta
  - (3) Strontium 90
- b. Plankton Populations
- c. Coliform Organisms
- d. Organic Chemicals

- Biochemical, chemical and physical measurements including biochemical oxygen demand (BOD), dissolved oxygen (DO), chemical oxygen demand (COD), chlorine demand, ammonia nitrogen, hydrogen ion concentration (pH), color, turbidity, temperature, alkalinity (or acidity), hardness, chloride, sulfate, and total dissolved solids.

#### L. Trace elements

Samples for radioactivity, coliform organisms, and the conventional analyses are collected and analyzed weekly. Samples for organic chemicals are examined monthly, while plankton organisms are examined monthly or semi-monthly. Strontium-90 examinations are made on composites of weekly samples accumulated over a three-month period. Trace elements are determined on 2-month composites of weekly samples. New parameters which are developed and found significant will be included as the program continues.

### ANALYTICAL METHODS AND RELIABILITY OF DATA

The physical, chemical and biochemical data included in this publication are the result of cooperative efforts of the several agencies listed in Table 1, column 6. In general most of these measurements were contributed by their laboratories. While it is recognized that modifications to meet local conditions are made by individual laboratories, the methods used in most cases are those published in the 18th Edition, "Standard Methods for the Examination of Water, Sewage, and Industrial Wastes." For orthotimony, the chlorine demand test is reported on the basis of the Starch-Iodide titration procedure, and the chemical oxygen demand test is restricted to the use of 0.5% N reagents.

To assure continued reliability in the published data, frequent analysis of reference samples by each cooperating

laboratory constitutes an integral part of the over-all program. Periodically a synthetic standard sample is provided to each participant for reference analysis. The reported results are reviewed. Any significant errors are called to the attention of the reporting laboratory and, after the cause of the errors has been determined, the previously submitted data are either corrected or discarded. From these findings, the analyses reported in this compilation are believed to be accurate to  $\pm 10\%$  of the reported values.

The analytical methods used by the Public Health Service laboratories are described in the discussion of water quality parameters which follows and are covered by several of the references listed in the Bibliography.

### WATER QUALITY PARAMETERS

In the assessment of water quality all of the legitimate purposes for which raw waters can be used, and which may be affected by pollution, must be considered. These may range from the minimum requirements necessary for navigation to the ultimate in water quality demanded for special industrial processing. Quality needs differ considerably therefore according to water use.

For domestic use, water must be free of disease organisms, clear, colorless, taste and odor-free and have a relatively low dissolved mineral content. Agricultural water is judged primarily on its mineral content, especially

with respect to the ratio between sodium and other cations and the presence of boron. Water for fish propagation and recreational purposes must be relatively free from domestic and industrial pollution and must be able to sustain an active flora of the smaller aquatic organisms on which fish and wildlife feed. Industrial water quality demands run the gamut from the complete absence of minerals to a requirement of low temperature. The critical factor in water used for cooling. The effects of radioactive materials on these uses have not yet been fully appraised.

The various laboratory examinations made as part of this program are discussed below.

## RADIOACTIVITY

Radioactivity, long recognized as a contaminant of water from natural sources, continues to grow in importance and health significance with the development of nuclear energy for both military and peaceful use. Background levels are being ascertained now ahead of the anticipated major expansion of the nuclear energy industry. Levels of radioactivity must be measured continually as new sources are established.

Gross alpha and beta measurements are made on both suspended and dissolved solids in the raw surface water samples. The total radioactivity in the dissolved solids provides a rough measure of the levels which may be found in a treated water, where water treatment removes substantially all of the suspended matter.

Alpha levels reflect the activity added by uranium and thorium daughters. Beta activity levels generally reflect the variable contamination due to fallout nuclear energy installations, institutions utilizing radioactive materials, and other man-made sources.

Gross levels are informative in evaluating long-term trends or changes in water quality. By themselves, however, they are of limited value in assessing radiation exposure. Where gross results are consistently over the maximum permissible concentrations for mixed fission products, the identity of the specific radionuclides involved must be established.

Because of the importance of Strontium-90 in the environment this year's data also includes the contribution of this long-lived radionuclide to the dissolved activity reported. The levels found were all well below the maximum permissible concentration as defined in Handbook 69 see Bibliography Reference No. 18.

## PLANKTON POPULATIONS

Many aquatic organisms are sensitive to the various substances which pollute water. Some of these develop only in relatively clean water while others may be stimulated to live and multiply in the presence of certain types of

pollutants, especially household sewage and certain types of industrial wastes. A very large population of algae is sometimes induced to develop by mineralized products of sewage decomposition when nitrates and phosphates are made available as nutrients.

The plankton data give the numbers, kinds, and times of occurrence of algae and other aquatic microorganisms in the water. This information is useful in determining the pollutional status of any water supply source, and in indicating the relative numbers of organisms which may cause problems in the treatment and use of water.

Most of these organisms interfere with water use through shortening of filter runs in treatment plants and by causing tastes, odors, coloration, and various physical and chemical changes. By reference to the plankton counts, made regularly and frequently, it is possible to note the types and numbers of interference organisms and to determine some of the procedures that will be needed in treating the water for use.

In the stream or lake itself many planktonic organisms are known to improve water quality by providing food and oxygen for desirable aquatic life and by aiding in the recovery of polluted water. Others may cause detrimental conditions through formation of unsightly blooms and mats, development of slime growths, and the killing of fish and other animals through the release of toxic products or other means.

Domestic and industrial wastes influence the kinds and numbers of organisms. Hence, plankton may reflect changes in water quality resulting from changes in the wastes containing dissolved substances.

Plankton counts will be particularly useful in water quality evaluation when they have been recorded over a period of time to indicate variations in kinds and numbers of organisms from month to month and from year to year.

### Reliability of Data

The counting procedures used are aimed at bringing about maximum accuracy in the reported data. The procedures

involve the simplification and standardization of methods of enumeration of each type of the many organisms observed. The actual volume of sample which is used for the analysis is relatively large and this tends to produce greater accuracy. Organisms are identified to genus, genus group, or species.

Each sample consists of three liters of raw water containing a preservative and, in addition, 25 ml. of raw water without preservative. Analysis for the macroplankton is made by counting a 104 mm strip on the Hodgewick-Haffner slide, using a magnification of 20X. From the live sample only kinds, not numbers of organisms are reported.

The drop counting method is employed on the preserved sample in which each solitary cell or colony of cells is counted as one. In order to improve reliability of data, plankton sampling has been increased from a monthly basis to a semi-monthly basis for 18 of the stations.

Because formalin as a preservative has a detrimental effect on some of the delicate organisms its use has been discontinued. Sodium ethyl mercuric thio-salicylate (MER-THIO-LATE) is now being used as a preservative.

No satisfactory method is at present available for separating the plankton organisms from the silt particles that are responsible for much of the turbidity in water and which also interfere with observation of plankton under the microscope. Accurate plankton analysis of water from turbid streams is therefore carried out with considerable difficulty.

#### Unusual Observations

In addition to the true plankton the benthic or bottom organisms are often present in the water, especially after periods of rainfall when the latter are washed in from their normal habitats. Examples include the stalked diatoms Denticulastrum, Achnanthes, and Cymbella, some motile forms of Navicula, and attached filamentous algae such as Stigeoclonium, Oedogonium and Ulothrix. Rain water also carries into the stream various fragments of tissues from land plants and animals. Pollen grains, mold spores, and plant hairs which drop into the water from the atmosphere are also frequently encountered.

Large populations of fungal hyphae and sheathed bacteria frequently appear. These sometimes follow blooms of planktonic algae or the presence of dispersed woody cells from terrestrial plants.

Metal and crystal particles, not associated with natural waters but dispersed in raw water samples have been found in a few samples during the examination for plankton. These particles have been traced for considerable distances through examination of downstream samples.

#### ORGANIC CHEMICALS

The Nation's water resources each year receive increasing quantities of organic contaminants. Since 1940 the chemical industry, particularly in the manufacture of synthetic and petro-chemicals, has experienced an enormous expansion that shows every sign of continuing. Each year millions of pounds of synthetic detergents, insecticides, herbicides, and similar domestic products find their way into our streams from household sewers, industrial waste discharges, and land runoff.

Effective and economical treatment methods for most of the complex organic materials remain to be developed. Even where treatment exists, residues remain in sufficient quantity to cause water damage. These stable residues persist through sewage treatment, biological and chemical action of the stream and water treatment processes and finally reach the consumer in drinking water.

The presence of some of these materials, even at concentrations less than 1 part per million, may cause impairment of water quality most noticeably in production of taste and odors. Fishfish baiting also quickly noticed by the consumer is another damage. Effects on water treatment many of which are ill-defined at present and impairment of water quality for industrial uses are being reported with increasing frequency. Essentially nothing is known of the possible immediate or long-term effects of these materials on human health. It is important that such information be sought.

The usual sanitary analyses are not effective in measuring these newer organic contaminants. Yet it is essential

to know something of their concentrations and character. The concentration method known as the "Carbon Filter Technique" developed by the Public Health Service permits the concentration of these organic compounds from a large volume of water. Elutriation of the adsorbed materials with organic solvents, followed by chemical separation and testing provides useful information concerning organic pollution and for assaying river systems for these substances.

It is difficult to say what part of the "total organic" content is measured, since there is no accurate method for measuring the low concentrations of organics. Work with known solutions has indicated that adsorption may be close to 100% and that desorption under the conditions of the test may range from 80% to 90%. The sampling and analytical techniques are reproducible with  $\pm 10\%$  when applied to replicate samples. Hence, relative pollutional loads on streams can be compared even though the absolute total quantity may not be accurately known.

Following continuous filtration of about 5000 gallons of water over a ten to fourteen day period, material on the carbon filter is extracted with two solvents, chloroform and alcohol.

The amounts of the chloroform and alcohol extracts are weighed, and the concentration of these materials in the water tested is then computed. Results are recorded in parts per billion (micrograms per liter). Clean waters may contain 20 to 50 ppb of chloroform extractables and 50 to 100 ppb of alcohol extractables. Polluted waters contain several times these concentrations.

#### Chloroform Extracts

The organic residues recovered from the carbon filter by chloroform is very complex. It is desirable to separate the crude extract into certain broad chemical classes and this can be done on the basis of solubility differences. The various classes or groups and their significance are discussed briefly below.

##### Ether Insolubles

This group is usually a brown, humus-like powder apparently composed to a large extent of carboxylic acids,

ketones and alcohols of complicated structure. Origin of the group which is an indicator of "old" pollution, is believed to be partially oxidized sewage and industrial wastes. For example the Ohio River at Cincinnati has been exposed to much industrial and sewage pollution, and hence large amounts of ether insoluble materials are found. Streams with little or no pollution history have little or no ether insolubles. Chloroform extracts contain from 0 to 30% of ether insoluble material.

##### Water Solubles

These substances are largely acids and undistillable at moderate temperatures, but their solubility in ether indicates that the molecules are smaller and probably simpler than the ether-insolubles. On the other hand, their water solubility practically requires the presence of several functional groups such as hydroxy-acid, keto-acid, and keto-alcohol. Such compounds probably originate from partial oxidation of hydrocarbons or they may be natural substances. These materials usually make up 10% to 20% of the total extract. They have very little odor.

##### Weak Acids

This group is characterized by being removed from ether solution with sodium hydroxide but not with sodium bicarbonate. Phenols are the best known weak acids and if present in the water appear in this group. Other weakly acidic compounds include certain amide imides sulfonamides and some sulfur compounds. This group of materials also occurs in nature. The weak acids commonly constitute 5% to 20% of the chloroform extract and they are odorous.

##### Strong Acids

These acids are usually the carboxylic acids such as acetic, benzoic, salicylic, or butyric. Although classified as strong in reference to carbonic acid, they are actually weak when compared with a mineral acid, such as sulfuric. Many of the compounds are used industrially but may also be produced by natural processes such as fermentation. This fraction makes up from 5% to 20% of the total. The significance of the strong acids can be interpreted only in the light of stream pollution conditions. Some of the materials are highly odorous.

### Bases

These compounds are organic amines. Such materials as aniline and pyridine are amines of commerce. Lower amines may occur as a result of decomposition. Generally only 1% or 2% of the total extract is made up of the bases. Although odorous, the low concentrations found are not likely to cause objectionable conditions. However, in the case of specific amine-containing wastes the compounds can be of considerable significance.

### Neutrals

This group frequently constitutes the major portion of the chloroform extract. Neither basic nor acidic, the materials are less reactive and tend to persist in streams longer than many other types. Hydrocarbons, aldehydes, ketones, esters, and others are examples of neutral materials. The group lends itself to further fractionation by means of chromatographic separation into aliphatic, aromatic and oxygenated sub-groups.

Aliphatics This portion represents petroleum type hydrocarbons in a considerable state of purity, and is usually made up of mineral oil type of material. The percentage of aliphatics present yields important information about the possible source of pollution since petroleum is the most likely source.

Aromatics These are principally the coal tar hydrocarbons such as benzene, toluene and a host of others and their presence in any significant amount is a reliable indication of industrial pollution. Further the materials can frequently be identified by infrared spectroscopy. Some aromatic compounds which have been found in our rivers - and in our drinking water - include DDT, aldrin, phenyl ether, ortho-nitrochlorobenzene, pyridine, phenol and others. The materials are highly odorous and may also be toxic. Their appearance in any quantity as pollutants should receive careful evaluation.

Oxygenated Compounds (Oxy's) These are the neutral compounds containing oxygen, such as aldehydes, ketones, and esters. They may have originated by direct discharge or may represent oxidation products from both natural

and industrial materials. They help to indicate the "age" of the pollution, since pollution exposed to oxidation forces for a long time would be expected to contain large amounts of oxy's. The oxy materials are odorous.

### Losses

Manipulative losses are inherent in this type of separation. If the loss amounts 10% to 15%, volatile components may have been lost from the sample. Such volatiles may have significance as pollutants.

### Alcohol Extracts

The alcohol extractable fraction generally consists of more polar materials than the chloroform extracts, and contains synthetic detergents, proteins, carbohydrates, and miscellaneous natural substances. These classes of substances are not quantitatively recovered by the alcohol. For example, the alcohol recovers only 20 to 30 percent of the synthetic detergents present. On waters of mixed industrial and domestic pollution, the chloroform and alcohol extractables may be about equal. On some streams where the industrial pollution is rather low and much natural pollution and sewage is present, the alcohol extractables may exceed the chloroform by a factor of 4 to 6.

The alcohol extract is usually water-soluble but not ether-soluble. Very little further chemical separation is practical on the material. Tests revealed that synthetic detergents make up 1% to 12% of the alcohol fraction.

### Other Tests

Infrared spectra are routinely prepared on the total chloroform and alcohol extracts. In addition spectra are prepared on the most significant groups such as the neutral, aliphatic, aromatic and oxygenated. These spectra reveal something of the chemical structure of the materials, indicate differences, and in certain instances provide a definite identification. In the case of the alcohol extracts the infrared will indicate the presence of synthetic detergents if the materials constitute a significant portion.

### Specific Identifications

During the course of the year numerous specific organic chemicals have been discovered in water samples. The chemical *o*-nitrochlorobenzene was found to persist in the Mississippi River for a distance of 1000 miles. Aldrin, a chlorinated insecticide was found in the Snake River. Various benzene derivatives and oil pollutants have been detected. See Bibliography, Reference A.

### CHEMICAL, PHYSICAL AND BACTERIOLOGICAL EXAMINATIONS

The various biochemical, chemical, and physical examinations generally performed by the participating laboratories are discussed below.

#### Ammonia Nitrogen and Chlorine Demand

The cost of water treatment for domestic use is affected by the consumption of chlorine, with ammonia nitrogen being responsible for a large portion of the chlorine demand. The greater this demand the more expensive the treatment. The ammonia may be due to unbalanced domestic pollution, to industrial waste discharges or to both. The presence of measurable quantities of nitrogen compounds, not necessarily ammonia, is also an indication of the fertility of the stream toward both macro- and microbiological forms.

#### Color

Color in domestic water supplies is undesirable. Its removal in the water treatment process, whether it be from natural or industrial sources, may require large doses of chemicals and be expensive.

#### Dissolved Oxygen, Biochemical and Chemical Oxygen Demands

Biochemical processes, in which aquatic organisms attack and stabilize the organic matter present require dissolved oxygen. If unstable oxidizable organic matter is

present in excess, the organisms will multiply rapidly, consuming the oxygen present in the water and bring about a foul septic stream condition. The dissolved oxygen level thus serves to indicate the biochemical activity of the stream. High activity, resulting in low dissolved oxygen levels, will drive out game fish in favor of scavengers. Very low or zero oxygen levels will kill all fish and aquatic organisms dependent on dissolved oxygen for life. Temperature and re-aeration rates also affect dissolved oxygen levels.

The 5-day biochemical oxygen demand (BOD) indicates the degree of unbalanced organic pollution from either domestic or industrial sources, to which the stream is being subjected. A significant demand will affect the fish and macroorganism population, and waters carrying a high BOD seldom contain game fish. On the other hand, game fish will thrive in streams in which the oxygen demand has been stabilized, as this condition is usually favorable for the growth of organisms on which fish feed.

The chemical oxygen demand analysis serves to support the findings of the biochemical oxygen demand test. It too may indicate to what extent the waste load of the stream has been stabilized, or it may indicate the presence of organic and inorganic pollution which is not readily oxidized by biological processes. Because the chemical oxygen demand can be determined quickly by comparison to the biochemical oxygen demand, the establishment of a correlation between the two parameters serves to reduce the number of the latter determinations required. The chemical demand results are almost always higher than the biochemical demand.

#### Temperature

Temperature is important to both conservation and industry. A few degrees elevation in temperature due to cooling water discharges may seriously limit the capacity of a stream to support fish life. Also, high water temperatures increase the cost of cooling water for industrial operations. Cooling tower capacities and other equipment for handling cooling water must be engineered to the temperature levels normally encountered.

### Mineral Constituents

These determinations include alkalinity, hydrogen-ion concentration (pH), hardness, chlorides, sulfates, and total dissolved solids. The pH indicates whether water is acidic or alkaline, corrosive or passive. Alkalinity is a measure of the neutralization reserve present, or the extent to which the water can resist a change from an alkaline to an acid condition upon addition of acidic chemicals. This information is important to the water treatment plant operator and to many other water users.

Hardness is not only a measure of the soap consuming property, but is also of importance in the treatment of boiler waters, where removal of hardness is one of the most important functions. Chloride, sulfate and total dissolved solids add further information on the gross dissolved mineral content carried by the stream. These are of great importance when considering the taste or palatability of water. They are also important when the water is being demineralized for specific industrial processes, since the cost of demineralization is a direct function of the dissolved solids content of the water. In addition waters of high sulfate content are less desirable and may at times even be unfit for municipal irrigation, and other uses.

### Turbidity

Turbidity of water is due to the suspension of clay silt, finely divided organic matter, microscopic organisms, and other similar materials. Its presence is of particular importance in water treatment processes and in the propagation of fish and other aquatic life.

### Coliform Organisms

Information regarding fecal pollution is essential to water quality measurements. Data on coliforms help to point up the trends in the effectiveness of control of domestic waste discharges.

The delayed incubation membrane filter technique is used for the coliform examinations, instead of the fermentation tube (MPN) method. The latter method would necessitate transportation of water samples to the labora-

tory for examination, resulting in an elapsed time between collection and examination which would change the microbial content of the samples significantly. Also some of the many other bacteria present in raw water might overgrow or otherwise inhibit the demonstration of the coliforms. In the delayed incubation membrane filter procedure, the bacterial organisms are removed from the fluid sample immediately and sent to the laboratory on a preservative medium. Thus the resulting coliform count approaches very closely the actual number of coliform bacteria present in the water sample at the time of collection.

### Trace Elements and other Determinations

This year's data include the examination of composite samples of raw water from each station for the dissolved constituents likely to be present in trace quantities or whose significance does not warrant more frequent analysis. Twice during the year, two-month composites of the weekly samples were prepared and subjected to analysis. Examinations covered those elements which were considered to have possible physiological or toxicological significance to biological life and for which a reliable method was available. As new methods are developed other determinations will be included. The ultimate goal of this phase of the program will be to provide background data on all elements which may be found in water and which can be detected by practical laboratory procedures.

Two series of samples are reported in this compilation. Although the first series does not exactly correspond with the beginning of the present water year, its collection was begun earlier in order to include low water conditions. Subsequent sampling and compositing periods will cover other ranges of stream flows.

In carrying out the spectrographic examination, the sample was first passed through a membrane filter to remove all suspended matter. An aliquot of the sample was then taken, acidified with hydrochloric acid, and evaporated to a concentration containing 2 mg. of solids in 0.1 ml. of sample (20,000 ppm). A 0.05 ml. portion of the concentrated sample was then placed on the electrode and arced to completion. Sample exposure was made through a stepped sector disc. The exposed plate was compared to a standard plate prepared under identical conditions.

Waters with low dissolved solids content can be concentrated to a greater degree than those having a high dissolved solids content, thus accounting for the apparently variable sensitivity shown in the tabulation. Values followed by an asterisk (\*) show the limits of sensitivity at which the test was performed, and indicate that the ion being measured was not detected at that level. The analyses done by wet or flame methods are quantitative and have been rounded off to the significant figures reported. The spectrographic analyses are semiquantitative and represent an approximation of the concentration present. All of the reported values by this method represent the quantity of the particular metal in solution at the time of examination. Hence such values do not consider what changes might have transpired in the sample during concentrating and stor-

age. Any interpretation based on these data should take this into account. It is well recognized that trace concentrations of many ions are subject to precipitation and adsorption on container surfaces during storage. This would particularly apply to iron and manganese, which are especially prone to oxidation and precipitation during storage. Suspended matter was not analyzed.

The colorimetric procedure, using osmium acid as detailed in the 10th Edition of "Standard Methods" was used for determining boron. Fluoride concentrations were made by the Bricchroma Cyanine R method, as given in Analytical Chemistry, 24:1161 (1954). The Chem Method, as given in Analytical Chemistry, 28:1738 (1956) was used for the Selenium Analyses.

### STREAM FLOWS

Stream flow records play an important part in utilizing water quality data such as covered in this report. However stream flow records have not been included in this compilation because they are readily available from the United States Geological Survey, the United States Corps of Engineers and other agencies.

The source of stream flow records is shown in Table 1 columns 7, 8, and 9. For each sampling point there is shown the location of the nearest stream gaging station, the operating agency, and the period of record.

## EXPLANATION OF DATA

### RADIOACTIVITY DETERMINATIONS

A dash in the column for the count signifies that that particular measure was not done.

### PLANKTON POPULATION

Blanks in any column are to be read as meaning that none of the organisms for that column were found. The

column heading "Dominant Organisms" should be interpreted in connection with the table below as follows: 5-946 should be interpreted that the fifth organism of the first column, Chlorella, was named. None of the organisms in the second column of the table was named. The 9 is the ninth item in the third column of the table - Stephanodiscus, 4 is the fourth item in the fourth column - Diatoma, and the 6 is the sixth item in the fifth column - Fragilaria. Five dashes in the column of "Dominant Organisms" mean that none was named for that report.

## PLANKTON--DOMINANT ORGANISMS

I	II	III	IV	V
1. Additional Filamentous Green Alga	Additional Green Flagellate	Actinastrum	Golenkinia	Additional Pigmented Flagellate (other than green)
2. Anabaena	Aphanizomenon	Additional Desmid	Additional Coccoid Green Alga	Additional Coccoid Blue-Green Alga
3. Asterionella	Cryptomonas	Anacystis	Chlamydomonas	Additional Diatoms
4. Cyclotella	Cyclotella	Ciliates	Diatoma	Additional Filamentous Blue-Green Alga
5. Chlorella	Gomphonema	Coelastrum	Cymbella	Ankistrodesmus
6. Cosmarium	Oscillatoria	Dinobryon	Nitzschia	Fragilaria
7. Synedra	Peridinium	Navicula	Synedra	Melosira
8. Euglena	Scenedesmus	Oocystis	Tabellaria	Micractinium
9. Phormidium	Unpigmented Flagellate	Stephanodiscus	Tribonema	Sarcodina

## ORGANIC CHEMICALS

The data entered relating to extractables are in micrograms per liter or parts per billion. Zeros when reported have been entered. A dash indicates that the respective results were not reported.

## CHEMICAL, PHYSICAL AND BACTERIOLOGICAL ANALYSES

The data entered in each column are as reported. A dash signifies that the particular test was not performed. Zeros

when meaningful have been entered. An asterisk preceding a coliform count should be read as "less than" the number following it.

## TRACE ELEMENTS AND OTHER DETERMINATIONS

For a discussion of the sensitivity limits of the determinations performed with spectrographic methods, see page 21.

[REDACTED]

[REDACTED]

## RADIOACTIVITY DETERMINATIONS

Gross radioactivity levels are informative in evaluating long-term trends or changes in water quality. By themselves, however, they are of limited value in assessing radiation exposure. Where gross results are consistently over the maximum permissible concentrations for mixed fission products, the identity of the specific radionuclides involved must be established. Because of the importance of Strontium-90 in the environment, this year's data also includes the contribution of this long-lived radionuclide to the dissolved activity reported. The levels found were all well below the maximum permissible concentration as defined in Handbook 69, see Bibliography Reference 18.

## WATER QUALITY BASIC DATA

STATE

ILLINOIS

MAJOR BASIN

OHIO RIVER

SUB BASIN

OHIO RIVER MAIN STEM &amp; MINOR TRIB.

STATION LOCATION

OHIO RIVER AT

CAIRO, ILLINOIS
